Design of Experiments (DOE) Tutorial - MoreSteam

The question of design of experiments is: which experiment is better? The variance of the estimate X_1 of θ_1 is σ^2 if we use the first experiment. But if we use the second experiment, the variance of the estimate given above is $\sigma^2/8$. Thus the second experiment gives us 8 times as much precision for the estimate of a single item, and estimates all items simultaneously, with the same precision.

One aspect which is critical to the design is that they be "balanced". A balanced design has an equal number of levels represented for each KPIV. We can confirm this in the design on the right by adding up the number of + and - marks in each column. We see that in each case, they equal 4 + and 4-values, therefore the design is balanced.
